COMPANY REFERENCE DATA SHEET

Trusted Reference Record for AI-Assisted Bid & Compliance Verification

Company Code	**COMP-001**	**Status**	**APPROVED**
Company Name	ABC Technologies Pvt Ltd	**Record Type**	Reference Company Record
Reference Use	Bid, vendor and document compliance verification	**Record Classification**	Demo / Controlled Reference Data

Purpose of this document. This reference data sheet is designed to act as a structured and human-readable source of trusted company information for an AI-assisted bid compliance verification system. It consolidates company identifiers, registration information, product specifications, certification records, and associated reference documents into one controlled record. During an audit, information extracted from a bidder's submitted documents can be compared against this reference record on a field-by-field basis.

Important data-quality note. This document intentionally contains an address inconsistency: the registered address states *Coimbatore, Tamil Nadu 600001*, while the supplied note identifies the correct city as *Chennai*. This discrepancy is retained deliberately as a test case for the verification system. The application should flag this information for review rather than silently correcting it.

1. Company Registration & Identifiers

Field	Reference Value	Verification Significance
Company Code	COMP-001	Internal reference key used to identify the company record.
Company Name	ABC Technologies Pvt Ltd	Used for company identification and name consistency checks.
GSTIN	33ABCDE1234F1Z5	High-value identifier for exact matching against submitted GST information.
CIN	U12345TN2020PTC123456	Company registration identifier used for entity verification.
Registration Number	REG-TN-2020-0981	Secondary registration reference for document comparison.
Registered Experience	5 Years	Can be compared with tender eligibility or bidder claims.
Contact Email	tenders@abctechnologies.com	Reference contact point for tender-related communication.
Contact Phone	+91-44-28394012	Reference contact number for record validation.
Registered Address	Plot 42, Electronics City Phase 1, Coimbatore, Tamil Nadu 600001	**Review required:** supplied note states the city should be Chennai.

The company registration and identifier section is the primary identity layer of the reference record. The company code COMP-001 provides an internal stable identifier that can be used by the reference API even if a company name is entered with a spelling variation. The GSTIN and CIN are particularly important because they are structured identifiers and should normally be evaluated using exact comparison rules. The registration number provides another reference value that can help resolve duplicate or ambiguous company names. Experience information can be compared with a tender's minimum eligibility requirement, while the email and telephone values provide supporting contact information.

The registered address requires special attention in this sample record. The address supplied in the source information contains the city name Coimbatore, although the accompanying note states that Chennai is intended. A compliance system should not overwrite either value without an authorized update. Instead, the discrepancy should be surfaced as a data-quality issue or manual-review item. This demonstrates why a reference database should preserve source values and why audit software should distinguish between a confirmed match and a value that requires verification.

2. Catalog Products & Specifications

Product	Model	Reference Specifications
Industrial Router	IR-500	Operating temperature from -10°C to 60°C; 5 Gigabit Ethernet Ports; 9-36V DC Redundant Power.
Network Switch	NS-24G	24 Port Managed Gigabit Switch; Layer 3 Routing.

The product section establishes the trusted catalog information against which technical bid submissions can be evaluated. For the Industrial Router, the model IR-500 is associated with a defined operating temperature range, five Gigabit Ethernet ports, and redundant 9-36V DC power. For the Network Switch, model NS-24G is associated with twenty-four managed Gigabit ports and Layer 3 routing capability. The verification system can extract product names, model numbers, and specifications from an uploaded technical document and compare them against these reference values.

Exact identifiers such as model numbers should normally be checked using deterministic comparison. Technical descriptions may require semantic comparison because the same requirement can be written in different ways. For example, an uploaded document might state 'temperature range -10 to 60 degrees Celsius' while the reference record states 'operating temperature from -10°C to 60°C'. A semantic comparison can recognize that these descriptions express the same range, while still preserving the original wording from both sources for audit transparency.

3. Reference Certificates & Documents

Document / Certificate	Status	Certificate Number	Validity
ISO 9001 Certificate	ACTIVE	ISO123456	Valid until 2027-08-15
GST Certificate	REFERENCE	—	Associated reference document
Technical Specification Sheet	REFERENCE	—	Associated reference document

The certificate section is intended to support both metadata-level and document-level verification. The ISO 9001 certificate is marked ACTIVE and has certificate number ISO123456 with a validity date of 15 August 2027. When an officer uploads an ISO certificate, the audit application can extract the certificate number, company name, certificate type, and validity date. These values can then be compared against the reference record. If the certificate number differs, the system should report a mismatch even if the company name and certificate type are identical. If the validity date has passed, the system should report an expired status based on the audit date.

The GST Certificate and Technical Specification Sheet are listed as associated reference documents. In a full implementation, each reference document should have a unique file identifier, storage location, upload timestamp, document type, and version. The database should store metadata rather than unnecessarily embedding large PDF files directly into ordinary database fields. The actual files can be maintained in controlled file or object storage, while the reference database stores their IDs and relationships to COMP-001.

4. Intended Use in the Compliance Verification System

This company reference sheet represents the trusted side of a two-source verification architecture. The officer's submitted documents belong to a separate submission workflow and should never be treated as trusted reference data simply because the information appears plausible. When a new audit begins, the system first stores the original submitted files and then extracts structured information using document-processing and AI capabilities. The extracted values are stored in a separate submission database associated with a unique audit or submission ID.

After extraction, the system identifies the relevant company using reliable identifiers such as GSTIN, CIN, registration number, or an approved company code. Once the company is identified, the main audit application calls the separate Reference Data API and retrieves the trusted record for COMP-001. The verification engine then compares the submitted data with the reference data field by field. This separation makes the audit process easier to trace because an auditor can see what the bidder submitted, what the trusted reference record contains, and exactly where the two differ.

The verification process should classify findings instead of producing only a single pass or fail result. A field can be marked MATCH when the values agree, MISMATCH when conflicting values are found, MISSING when a required submitted value is absent, NOT FOUND when the reference system has no corresponding record, EXPIRED when a certificate is no longer valid, or REQUIRES REVIEW when the system cannot establish a reliable conclusion automatically. These statuses make the final report more useful to an officer because they identify the exact reason for attention.

5. Example Verification Scenarios

Scenario	Submitted Value	Reference Value	Expected Result
GSTIN	33ABCDE1234F1Z5	33ABCDE1234F1Z5	MATCH
ISO Certificate No.	ISO999999	ISO123456	MISMATCH
Router Model	IR-500	IR-500	MATCH
Reference Company	XYZ Industries	ABC Technologies Pvt Ltd	MISMATCH / REVIEW
Registered Address City	Chennai	Coimbatore*	DATA-QUALITY REVIEW

* The address discrepancy is intentionally present in the supplied reference data and should be flagged for review.

6. Data Governance and Audit Integrity

Reference information should be maintained through an authorized administration interface rather than being directly editable by ordinary officers. Every company record should have a stable company code, document identifiers, version information, and update history. When a certificate is replaced or a company detail is corrected, the system should preserve sufficient history to determine which reference version was used for a particular audit. This is especially important when a verification result may later need to be reviewed.

The reference API should be protected by authentication and should expose only the information necessary for verification. The main audit application should not directly manipulate the reference database. Instead, it should request the required company record and reference documents through the API. This separation reduces the risk of

accidental modification and makes it possible to host the reference portal independently from the officer-facing audit application.

AI should assist with document understanding and semantic interpretation, but exact identifiers and critical compliance fields should be checked with deterministic rules wherever possible. For example, GSTIN, CIN, certificate numbers, dates, and model numbers can be compared directly. Gemini or another AI service can help interpret differently worded technical specifications and produce a concise explanation of findings. The final report should retain the original submitted value and the reference value so that an officer can independently understand why a finding was generated.

7. Reference Record Summary

COMP-001 is an approved sample reference company record for ABC Technologies Pvt Ltd. It contains registration identifiers, contact details, a product catalog, an active ISO 9001 certificate, and associated GST and technical documents. The record is intentionally suitable for demonstrating both successful matches and exception handling. In particular, the address inconsistency and the possibility of a certificate-number mismatch provide realistic test conditions for the compliance verification workflow.

When integrated into the complete application, this sheet represents the trusted reference side of the process. An officer's submitted documents should be extracted into a separate submission record. The system should then locate COMP-001 through the reference API, retrieve the relevant trusted values and documents, compare them individually, classify every finding, and generate a downloadable audit report. The resulting report should make a clear distinction between automatically matched information and items that require human review.

Reference status: APPROVED for controlled demonstration/testing purposes. This sample record is not an official government or corporate certificate and should not be used as evidence of real-world company registration, certification, eligibility, or procurement status.
